Congenital rubella and rubella in pregnancy news

Congenital rubella and rubella in pregnancy surveillance report

Rubella and congenital rubella syndrome elimination by 2020 in the European Region of the World Health Organization (WHO-EURO) is included among the objectives of the “European Vaccine Action Plan 2015-2020”.

In Italy a national surveillance system of congenital rubella and rubella infections in pregnancy is active since 2005 in order to monitor progress toward elimination.

This report shows national and regional surveillance data for the period January 2005 - August 2017. Reclassification of some cases due to updated information may be responsible for minor variation of data respect to the previous bulletins.

Highlights

• In the period January 2005 - August 2017, 87 congenital rubella infections (probable and confirmed cases) were reported, with two peaks in 2008 and 2012.

• Moreover 173 rubella infections in pregnancy (possible, probable and confirmed cases) were notified. Among them, 32 voluntary terminations, 1 stillbirth and 1 spontaneous abortion were reported.

• In the first 8 months of 2017 two congenital rubella cases (1 confirmed and 1 probable) and one confirmed case of rubella in pregnancy were reported.

• Congenital rubella incidence is below 1 case per 100,000 live births since 2013. It is, however, necessary to keep high the attention, taking into consideration that rubella infection has a cyclic-epidemic trend.

• It is necessary to reinforce the follow up of the outcome of pregnancies and of the status of infection of the newborns with suspected congenital rubella over time.

The report is available online at: http://www.epicentro.iss.it/problemi/rosolegia/bollettino.asp
In the period January 2005 – August 2017, 87 cases of congenital rubella were reported: 78 confirmed and 9 probable cases according to European Commission case definition.

Furthermore, we received 66 notifications of suspected cases that we could not classify because of lack of information or because these cases were not monitored over time.

Figure 1 shows the number of congenital infections (confirmed and probable cases) by year and classification. We can observe a peak of notifications in 2008 (30 cases, with an incidence of 5.2 per 100,000 live births) and one in 2012 (21 cases, with an incidence of 3.9 per 100,000 live births).

In the first 8 months of 2017, two congenital rubella cases (1 confirmed and 1 probable) were reported.

Clinical information
Information on clinical manifestations are available for 81 of the 87 probable/confirmed reported cases.

At least one clinical manifestation was reported for 65 cases. The most frequently reported symptoms/sign were:

- Congenital heart disease (45 children)
- Loss of hearing (30 children)
- Cataract (13 children)
- Meningoencephalitis (12 children)
- Microcephaly (11 children)

Twenty-two cases had multiple defects involving the heart, hearing or vision.

Sixteen infants were asymptomatic: they are cases with laboratory confirmation and epidemiological link.
Rubella in pregnancy: national data

In the period January 2005 – August 2017, 173 cases of rubella in pregnancy (160 confirmed, 9 probable and 4 possible cases) were reported.

In addition, we received 106 notifications of suspected cases that we were unable to classify with the available information.

In the same period, among the infected women, one stillbirth, one spontaneous abortion and 32 voluntary terminations were reported.

The Figure 2 reports the number of rubella infections in pregnancy (confirmed, probable and possible cases) by year and case classification. We can observe a peak of notifications in 2008 (78 cases) and one in 2012 (51 cases). This temporal trend is consistent with that reported for congenital rubella in the Figure 1.

In the first 8 months of 2017, one case of rubella infection in pregnancy was reported.

**Figure 2. Rubella in pregnancy by year and classification. Italy, January 2005 – August 2017**

- The median age is 27 years
- 17% (28/167) is not Italian
- 42% (48/115) acquired the infection in the first trimester of pregnancy
- Only 29% (38/133) performed the rubella antibody screening before pregnancy
- 45% (70/160) had previous pregnancies (Figure 3)
- Three women reported to be vaccinated (but the vaccination history is not documented)
- For 40 women (23%) it is unknown if the infection was transmitted to the newborn, because the outcome of the pregnancy is unknown or because information regarding the status of infection of the newborn was not available.

**Figure 3. N. previous pregnancies in infected women**

The report is available online at: http://www.epicentro.iss.it/problemi/rosolia/bollettino.asp
In the first eight months of 2017 two congenital rubella cases (1 confirmed and 1 probable) and one confirmed case of rubella infection in pregnancy were reported. Additionally one suspected case of congenital rubella, not yet classified, was reported. Specifically these are:

- **one confirmed case of congenital rubella syndrome**, born from a nulliparous woman, living in a reception centre for migrants, with a confirmed infection in pregnancy. The woman did not report to have travelled or stayed in foreign countries during the infection incubation period. The newborn, at birth, had patent ductus arteriosus, ventricular septal defect, splenomegaly, purpura and brain cysts.

- **one probable congenital rubella case**, born from a multiparous unvaccinated woman, living in a reception centre for migrants, with a confirmed infection in pregnancy (reported to the national surveillance system in 2016). The newborn, at birth, had patent ductus arteriosus. The woman did not report to have travelled or stayed in foreign countries during the infection incubation period.

- **a suspected congenital rubella case**, born from a multiparous unvaccinated woman, living in a reception centre for migrants, who contracted the infection before arriving in Italy (imported case). This case has not been classified yet because follow up information was not available at the time of this report. However, the baby, at birth, had no sign/symptom consistent with congenital rubella and rubella specific IgM were negative; even the diagnostic ascertainment conducted in the prenatal period had not detected any fetal infection.

- **a confirmed indigenous infection of rubella in pregnancy**, in a nulliparous unvaccinated not Italian woman. Diagnosis of infection was made in the sixth week of pregnancy. The follow up of this case is ongoing.
The surveillance system for congenital rubella and rubella in pregnancy

In Italy the notification of congenital rubella syndrome, congenital rubella infections and rubella infections in pregnancy is mandatory since the 1st of January 2005.

The national surveillance system for congenital rubella and rubella in pregnancy is mandatory, passive, case-based and based on clinicians.

Two separate notification forms are used for congenital rubella and rubella infections in pregnancy; the notification form for congenital rubella also includes a section regarding the mother’s history.

Data flow is described below.
**To improve the surveillance...**

- Improving the sensitivity and specificity of the surveillance system is important to monitor progresses towards elimination.
- An annual/biannual crosscheck between notifications and hospital records with 771.0 discharge code should allow to detect congenital rubella cases not reported to the surveillance system.
- Clinicians’ awareness on the importance of reporting all cases to the surveillance system should be arisen.
- Strengthening the surveillance of pregnant women with suspected rubella infection is fundamental because it is an entry point for congenital rubella cases. Early diagnosis of congenital rubella cases also allows quick interventions for any associated defect and prevention of rubella spread from infected infants.
- Monitoring of infected pregnant women is also important to record all the outcomes of the pregnancy, including stillbirth, spontaneous and voluntary terminations, that contribute to assess the burden of congenital rubella.
- It is important that all the babies born from mothers with possible, probable and confirmed infection in pregnancy are followed up over time with laboratory, clinical and diagnostic investigations, in order to confirm or exclude the congenital infection and correctly classify the cases as infection or syndrome. It is necessary to improve the timeliness of the collection of clinical information and laboratory results and their completeness, in order to reduce the amount of cases that cannot be classified.
- A monthly report of congenital infections and infections in pregnancy, including zero-reporting, is needed to improve the sensitivity and the timeliness of the surveillance system.
